Angioedema as a single manifestation of carcinoid syndrome in a bronchial carcinoid tumor

*Allergy Department. †Pneumology Department. San Pedro de Alcántara Hospital. Cáceres. Spain.

ABSTRACT

Background: The association of bronchial carcinoid tumours with carcinoid syndrome is extremely rare especially in the absence of metastatic disease, and the angioedema is not a typical sign of this syndrome.

Methods and results: We report the case of a 39 year-old woman referred to our allergy department with recurrent episodes of angioedema. The aetiological study of angioedema did not show evidence of hypersensitivity to common inhalants, food allergens and latex. C1-inhibitor, C3, C4, C1q, proteinogram and immunoglobulins (IgA, IgG, IgM) all were normal. TSH determination gave normal results, too. Faecal analyses for parasites were negative. The haemogram showed moderate leucocytosis and hypocromic microcitic anaemia. The thoracic radiography showed a mediastinal node image in the right paratracheal region. Histology analyses of the samples were diagnostic of a typical carcinoid tumor. Levels of 5-hydroxyindolacetic acid (5-HIIA) were slightly increased. A superior lobectomy was performed and no new episodes of angioedema appeared after surgical intervention.

Conclusions: We report the first case of typical bronchial carcinoid tumour, without metastatic disease, with angioedema as a single manifestation of carcinoid syndrome.

In our knowledge, only one case of Quincke’s edema as part of typical carcinoid syndrome has been reported, in a case of primary midgut carcinoid tumor with metastatic disease to liver. It is very important to include complementary tests, as thoracic radiography, in the routine study of angioedema to reject malignant diseases.

Key words: Angioedema. Carcinoid syndrome. Carcinoid tumor. Thorax radiography.

RESUMEN

La presencia de síndrome carcinoide asociado a tumores bronquiales es poco frecuente, sobre todo en ausencia de enfermedad metastásica; y el angioedema no es una manifestación típica de dicho síndrome.

Métodos y resultados: Presentamos el caso de una paciente de 39 años de edad con episodios recuentes de angioedema.

En el estudio etiológico de angioedema no se evidenció hipersensibilidad frente a inhalantes, alimentos ni látex. La determinación de fracciones séricas de complemento (C3, C4, C1q y C1-inhibidor) e inmunoglobulinas mostró resultados normales. Los va
lores de TSH estaban, asimismo, dentro de la normalidad. En análisis de parásitos en heces fue negativo. En el hemograma se apreciaba una leucocitosis moderada y una anemia microcítica e hipocromía. La radiografía de tórax mostraba una imagen nodular mediastínica a nivel paratraqueal derecho. El estudio histológico fue diagnóstico para carcinoid típico. Los niveles de ácido 5-hidroxiindolacético (5-HIIA) en orina de 24 horas, estaban discretamente elevados. A la paciente se le practicó una lobectomía superior derecha, no volviéndose a presentar nuevos episodios de angioedema tras la intervención.

Conclusiones: Presentamos el primer caso de tumor carcinoide bronquial típico, sin enfermedad metastásica asociada, con angioedema como única manifestación de síndrome carcinoide. Sólo tenemos conocimiento de un caso de edema angioneurótico de Quincke asociado a síndrome carcinoide en un caso de tumor primario intestinal con metástasis hepáticas. Creemos que es importante incluir determinados exámenes complementarios, como la radiografía de tórax, en el estudio de rutina del angioedema para descartar enfermedades malignas subyacentes.

Palabras clave: Angioedema. Síndrome carcinoide. Tumor carcinoide. Radiografía de tórax.

INTRODUCTION

Carcinoid tumours are neoplasms of the neuroendocrine system. They are usually small in size and slow growing. They can be found in different locations, such as intestines, respiratory airways, the urinary system and gonads. The incidence varies depending on the series, although it is estimated that it is about 1.5 per 100,000 inhabitants. They are more frequent in women than in men (1.6:1) and are not related to smoking. Almost 2% of the bronchial tumours are carcinoids.

In the majority of cases, they are accidentally found in necropsies and in surgical operations because they do not show any symptoms. There are two kinds of carcinoid tumours, the so-called “typical”, with a high degree of differentiation, and the “atypical”, with a major mitotic activity and a tendency to metastasize. Like neuroendocrine tumours, the carcinoids synthesize biogenic amines that develop the carcinoid syndrome when they are released into the systemic circulation. This syndrome is characterized by diarrhoea, flushing and pain, although other atypical manifestations, such as wheezing or cardiac failure, are possible. Although not in every case, in the majority of cases, the syndrome is developed in the presence of liver metastasis.

The association of bronchial carcinoid tumours with carcinoïd syndrome is extremely rare especially in the absence of metastatic disease, and the angioedema is not a typical sign of this syndrome.

CASE REPORT

We report the case of a 39 year-old woman, a smoker, referred to our allergy department with recurrent episodes of angioedema for the last six months. Angioedema occurs in different locations, including eyelids, lips, and soles, on different occasions; which spontaneously disappeared after one day.

The aetiological study of angioedema did not show evidence of hypersensitivity to common inhalants, food allergens and latex. C1-inhibitor, C3, C4, C1q, proteinogram and immunoglobulins (IgA, IgG, IgM) all were normal. TSH determination gave normal results, too. Faecal analyses for parasites were negative. The haemogram showed moderate leucocytosis and hypocromic microcitic anemia. As such, a carcinoid tumor was suspected as the cause of angioedema episodes, as a carcinoid syndrome manifestation. Certainly, levels of 5-hydroxyindolacetic acid (5-HIIA) were slightly increased, 11.1 mg/day, respect to normal values between 2-8 mg/day. Determination of serotonin in platelets gave normal results. A superior lobectomy was performed and, as suspected, no new episodes of angioedema appeared after surgical intervention.

DISCUSSION

Patients with classic carcinoid syndrome usually present diarrhoea, flushing and localised or generalised pain. Biogenic amines such as serotonin, hist-
amine, kallikrein, substance P, prostaglandins and catecholamines are excessively synthesized, stored and released into the systemic circulation.

Some of them, mainly histamine, are implicated in the pathogenesis of the angioedema, possibly manifesting itself as a part of a carcinoid syndrome. The histamine is the predominant mediator in angioedema, because the quantities in blood are 100 to 1000 times higher than the others constituents.

Until Feldman et al reported in 1982 three cases of carcinoid syndrome without liver metastasis, only carcinoid tumours with metastatic disease had been associated to this clinical situation. It is of interest that gastrointestinal carcinoids usually produce the syndrome only when they spread to the liver, because from there they can release tumour products into the systemic circulation avoiding liver breakdown, and metastasize to the lungs, bones and other organs.

But, as said, the development of the syndrome is possible in the absence of metastasis, if the tumour discharges the active products directly into the systemic circulation and circumvents hepatic metabolism. This situation is possible in extra-intestinal locations such as lung, gonads and the retroperitoneum.

Carcinoid tumors arising in the lung specifically produce serotonin, gastrin, adrenocorticotropic hormone and histamine, probably involved in the gene expression of bronchial carcinoid tumors with carcinoid syndrome, only in one patient with metastasic disease. The carcinoid syndrome is extremely rare and it has been reported in only one patient with metastatic disease. Acquired angioedema has been reported as a manifestation of malignant disease in monoclonal gammopathies by auto-antibodies against C1-inhibitor, but in the best of our knowledge, only one case of Quincke’s edema as part of typical carcinoid syndrome in the absence of liver metastasis. A case report and review of the literature. Chest 2001;119(6):1647-51.

In conclusion, we report the first case of typical bronchial carcinoid tumour, without metastatic disease, with angioedema as a single manifestation of carcinoid syndrome. So, it is very important to include complementary tests in the routine study of angioedema to reject malignant diseases. In our case, the thoracic radiography was the basis of the diagnosis of recurrent angioedema due to bronchial carcinoid tumor.
