Intercoronary communication

Abstract  Intercoronary communication is a very rare coronary artery anomaly. It is defined as an open-ended circulation with bidirectional blood flow between two coronary arteries. Coronary artery fistulas are abnormal communications between a coronary artery and a cardiac chamber or major vessel. A 62-year-old man was admitted to our hospital with sudden development of general weakness, dizziness and a sensation of compression in his chest. At presentation his blood pressure was 80/40 mmHg and heart rate was 65 beats/min. The ECG revealed sinus rhythm and 1–2 mm ST elevation in the anterior leads. The patient was taken to the catheterization laboratory for percutaneous coronary intervention. The left main and left circumflex coronary arteries were normal. Coronary angiography showed a communication between the left main and the diagonal branch of the left anterior descending and a fistula between the intercoronary connection and the left atrium. The other coronary arteries were normal. Laboratory test results, including cardiac troponin I and creatine kinase-MB levels, were normal. The angina symptoms disappeared and the ST elevation resolved within four hours. We report an interesting case of congenital coronary artery fistula in an intercoronary communication between the left main and the diagonal branch of the left anterior descending coronary artery presenting as an acute coronary syndrome. To the best of our knowledge, this is the first case in the literature involving a coronary artery fistula in an intercoronary communication.

Introduction

Intercorony communication is a very rare coronary artery anomaly, with a prevalence of 2.37/100 000. It is defined as an open-ended circulation with bidirectional blood flow between two coronary arteries. It can be distinguished from collateral arteries by its angiographic features, and in itself does not usually reflect underlying coronary artery disease. Intercorony arterial connections are thought to be congenital in origin. Compared with collaterals, intercorony arterial connections are larger in diameter (>1 mm), extramural, and straight. Furthermore, the structure of an intercorony arterial connection is typical of an epicardial coronary artery, with a well-defined muscular layer.

Coronary artery fistulas are abnormal communications between a coronary artery and a cardiac chamber or major vessel. They may be congenital or acquired due to trauma or iatrogenic causes. Angiographic series reveal an incidence of coronary artery fistula in adults of 0.3-0.8%. Most of these patients are asymptomatic, but heart failure, angina, myocardial infarction, coronary steal, endocarditis, and dyspnea have been reported.

We report an interesting case of congenital coronary artery fistula in an intercorony communication between the left main and the diagonal branch of the left anterior descending coronary artery presenting as an acute coronary syndrome.

To the best of our knowledge, this is the first case in the literature involving a coronary artery fistula in an intercorony communication.

Case report

A 62-year-old man was admitted to our hospital with sudden development of general weakness, dizziness and a sensation of compression in his chest. He had a history of diabetes mellitus. At presentation his blood pressure was 80/40 mmHg and heart rate was 65 beats/min. The ECG revealed sinus rhythm and 1–2 mm ST elevation in the anterior leads (Figure 1). The patient was taken to the catheterization laboratory for percutaneous coronary intervention. The left main and left circumflex coronary arteries were normal. Coronary angiography showed a communication between the left main and the diagonal branch of the left anterior descending and a fistula between the intercorony connection and the left atrium (Figure 2). The other coronary arteries were normal. Laboratory test results, including cardiac troponin I and creatine kinase–MB levels, were normal. The angina symptoms disappeared and the ST elevation resolved within four hours (Figure 3). To the best of our knowledge, this is the first case in the literature involving a congenital coronary artery fistula in an intercorony communication.

Discussion

The hemodynamic consequences of coronary artery fistulas are variable depending on shunt size, site of the shunt and presence of other underlying heart disease. Fifty percent of patients with large or multiple fistulas may develop complications, which may include bacterial...
Congenital coronary artery fistula

Figure 1  Electrocardiogram revealing 1–2 mm ST elevation in the anterior leads.

Figure 2  Contrast injection in the left coronary artery showing a large connection between the left main and the diagonal branch of the left anterior descending (black arrow) and a fistula between the intercoronary connection and the left atrium (white arrow). D: diagonal; LM: left main.

endocarditis, thrombosis, aneurysm formation, dissection, rupture, premature atherosclerosis, pulmonary hypertension, myocardial ischemia, or infarction.9

The functional significance of large intercoronary communications between normal coronary arteries is unclear but one may speculate that they have a potential role in protecting the myocardium should significant atherosclerosis develop in either of the patent arteries4; on the other hand, myocardial ischemia could result if an unidirectional intercoronary communication causes a coronary steal phenomenon that results in inadequate perfusion.10

The ischemic consequences of an intercoronary connection with unidirectional flow may be explained by its similarity to a fistula from a coronary artery to a low-pressure cardiac space.11

We believe that an intercoronary communication between the left main and the diagonal branch of the left anterior descending coronary artery and a congenital coronary artery fistula may be the cause of ischemia in this case.
